100 FIG. 3A Telephone call arrives 110 at a voice response unit port. 120 Voice response system collects data, including an ANI for each call. 125 Upon determination that a call requires connection to an operator terminal, the voice response unit generates and transmits a message to a voice response unit interface including the data and ANI for the call. The voice response unit interface stores 130 the data in interface unit memory and stores the ANI in a lookup table. The voice response unit interface sends a 135 response to the voice response system indicating that the data has been successfully received and stored. Upon receipt of a response, the voice 140 response system transfers the call to at least one specified queue configured the to hold the call. 150 A data controller monitors the specified queue(s) to identify the receipt of calls.

FIG. 3B 160 The data controller identifies an ANI for each call identified in the specified queue(s). 170 The data controller compares the ANI of each call in the specified queue(s) with the ANIs stored in the lookup table in the voice response unit interface to determine if a match exists. 180 If a match exists, the data controller retrieves the data from the interface memory and provides the same to an operator terminal assigned to handle the call. 190 The interface removes the ANI from the lookup table. If no match, call did not come from voice 200 response system. Call center management system processes call in ordinary manner.
